BUILD GUIDE

Display Evaluation Kit

K_MSP430

For

4.0", 4.7", 4.9", and 10.7" Plastic Logic Displays

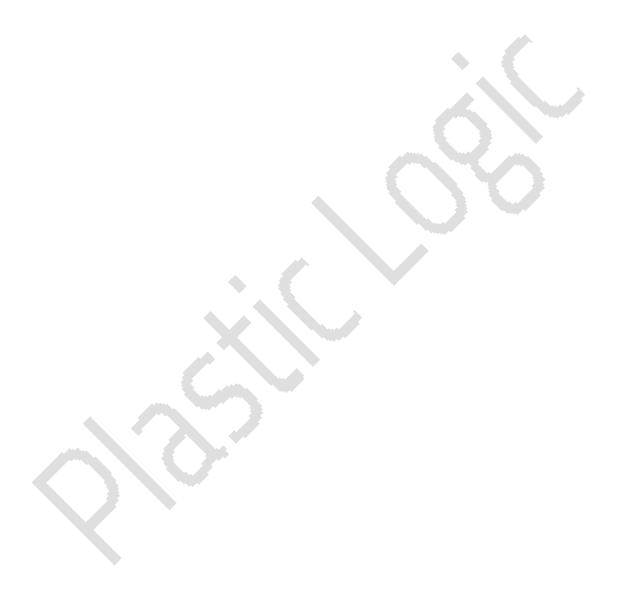

Part No.: 303002, 303004, 303006, 303010

Containing Part No. 301008 and 301002, 301014 or 301015

Revision 1 February 15th 2018

PLASTIC LOGIC

2 Introduction

This document provides an introduction how to set up a build environment and how to set up the development software. The project is in active development and feedback is welcomed on new features or issues found in the code or documentation. Please send feedback via your sales/support representative.

3 Glossary

CCS

Code Composer Studio, an integrated development environment from Texas Instruments that can be used to develop code for the MSP430 microcontroller

EPD

Electrophoretic display. Such displays retain the last image driven to them and only require power to change the image

EPDC

Electrophoretic display controller. A specialized display timing controller required for updating electrophoretic displays. The EPDC is responsible for applying the correct waveform to each pixel, according to the current and target images

FFC

Flexible flat cable (http://en.wikipedia.org/wiki/Flat_Flex_Cable)

Mercury / Hermes / Sojus board

An interface board from Plastic Logic that connects a Plastic Logic 10.7" display (e.g. D107_T3.1) to a Raven board via a 50-way FFC

MSP430

A low-power microcontroller from Texas Instruments

Parrot board

An evaluation board from Plastic Logic containing a MSP430 microcontroller

S1D13524

An EPD controller chip from Epson, designed for use with displays up to a resolution of 4096x4096 pixels. Also supports color displays

S1D13541

A combined EPD controller chip and source driver from Epson, designed for use with displays up to a resolution of 854x480 pixels

USCI

Universal Serial Communication Interface. MSP430 serial communications interface that supports multiple serial communication modes with one hardware module

PL-AE-BuildGuide-002868

All rights reserved.

Revision 1

VCOM

Display-specific common electrode voltage. Each Plastic Logic display is supplied with the correct voltage that must be applied by the control electronics

Waveform

A display-specific data file that defines how the display updates

4 Getting Started

This section covers setting up the hardware and software so that a given display type can be driven. Please follow the steps outlined in order to setup and build the software.

4.1 Get the Code

Get the source code, either by downloading an archive or cloning the repository:

git clone https://github.com/plasticlogic/pl-mcu-epd.git

It is recommended to use the most recent version branch. For compatibility reasons, the former versions are available as well.

4.2 Code Composer Studio Setup

The Plastic Logic reference code project uses Texas Instruments' Code Composer Studio IDE v5.5. This section details the steps necessary to set up Code Composer Studio to build and debug the code.

Important

This project uses **DOS** line endings. The .gitattributes file tells Git to automatically convert text file line endings to DOS at commit time. To avoid complications on Unix-like operating systems (Linux, MacOSX...) please configure your text editor to use DOS line endings.

- 1. Install Code Composer Studio from TI on MS Windows or GNU/Linux
- 2. Create new CCS project

Open the menu File -> New -> CCS Project

Project name: pl-mcu-epd (for example)

Project location: Ensure the location is different to that of the cloned repository

Output: Executable

Device family: MSP430

Variant: MSP430F5438A (for PL Parrot v1.x boards)

Connection: TI MSP430 USB1 (uses an MSP-FET430UIF USB-JTAG interface)

Project template: Empty Project

3. Import the source code

Open the menu File -> Import -> General

To import a clone repository, choose File System

To import a source archive, choose Archive File

Note

When using a source archive, the source will need to be moved out of the extra sub-directory that is created.

Browse to select your pl-mcu-epd cloned repository or archive file

Select all the files (checkbox near pl-mcu-epd)

Click on Finish

4. Compiler configuration

Open the menu **Project -> Properties**

Click on the Show Advanced Settings link in the bottom left of the properties window

The following project settings need to be modified:

CCS Build -> MSP430 Compiler -> Debug Options

Debugging Model: Should be set to 'Full Symbolic Debug'

CCS Build -> MSP430 Compiler -> Advanced Options -> Language Options:

Check the box for Enable Support for GCC Extensions

CCS Build -> MSP430 Compiler -> Advanced Options -> Library Function

Set the level of printf support to **nofloat**

CCS Build -> MSP430 Compiler -> ULP Advisor:

Disable the following items by unchecking the associated box:

2: Software (SW) delay

5: Processing/power intensive operations

CCS Build -> MSP430 Compiler -> Advanced Options -> Diagnostic Options:

Check the box for Emit Diagnostic Identifier Numbers

CCS Build -> MSP430 Linker -> Basic Options

Set C system stack size: 160

Heap size for C/C++ dynamic memory allocation: 1000

C/C++ General -> Paths and Symbols

Includes: Add the following paths to the includes list (check all three boxes in the creation dialog window)

/\${ProjName}/msp430

/\${ProjName}

Includes: Re-order the includes list so that the order is as below:

/\${ProjName}/msp430

\${CCS_BASE_ROOT}/msp430/include

/\${ProjName}

\${CG_TOOL_ROOT}/include

5. Setup config.txt

Finally, a config.txt file must be placed on the SD-Card. A sample config file is supplied for each supported display type. More information on the various code configuration options can be found in the section Configuring the Code.

4.3 SD Card Setup

The micro SD card for the processor board must be formatted as a FAT/FAT16 file-system (not FAT32). The SD card contents (initialization data and images) can be retrieved from the Plastic Logic GitHub repository

git clone https://github.com/plasticlogic/pl-mcu-sd-card.git

Make sure to use the same version for the SD-Card branch as used for the source code. I.e. the code version V11 is not compatible to SD-Card -content version V10 and vice versa

Unzip this archive and place the resulting files on the SD card so that the root directory of the file-system contains the folders D107_T3.1, S040_T1.1, etc. The supplied content provides a safe set of configuration data for each type of display. In order to obtain the best image quality the waveform binary file, waveform.bin (for S1D13541) or waveform.wbf (for S1D13524), and the text file vcom, containing the VCOM voltage in mV, must be replaced with data specific to the display used. These files are located at:

```
0:/<Display-Type>/display/waveform.bin
0:/<Display-Type>/display/waveform.wbf
0:/<Display-Type>/display/vcom
```

Place the micro SD card in the micro SD card socket on the processor board.

4.4 Running the Code

Once the code has been configured and built in Code Composer Studio, the resulting binary can be transferred to the Parrot board using the MSP-FET430UIF USB-JTAG programmer. Depending on the configuration, you should now be able to see one of the following: • A slideshow of stock images from the 0:/<Display-Type>/img folder being shown on the display until execution is halted (with or without power sequencing). The slideshow will skip any files that do not have the extension ".pgm"

- A sequence of images defined by the 0:/<Display-Type>/img/slides.txt file
- A checkerboard image

4.5 Toolchains

4.5.1 Code Composer Studio

Code Composer Studio has been used extensively during development of the code in conjunction with the MSP-FET430UIF USB/JTAG programmer. Both have proved to be extremely reliable in use. There is a free version of the tools which restrict the size of code they will generate to 16KB. The full version can be evaluated free for 90 days. The current configuration of the code is too large to fit within the 16K limit, however by removing some features, e.g. Fat file system support then the free version may be sufficient. A very useful feature of the IDE is the ability to use standard printf type functions and have the output displayed in a console window within the IDE. In order for this to work the amount of memory set aside for the stack and heap must be increased and the io functionality must be enabled in the project build configuration. A small amount of source code in the platform common layer was taken from Plastic Logics equivalent Linux drivers. The code uses anonymous unions extensively and in order to get the code to compile it was necessary to add a compiler flag (--gcc) to tell it to behave more like gcc.

4.5.2 msp430-gcc

There is an open source msp430 tool chain available "msp430-gcc". Some work has been done to support this tool chain but the work is not yet complete. Much of the code compiles cleanly however there are some issues related to pragmas used to declare interrupt handlers. Full support for this tool chain will depend on customer demand.
